Persistent Organic Pollutants Review Committee

Second meeting

Geneva, 6–10 November 2006

Item 6 (b) of the provisional agenda*

**Consideration of chemicals newly proposed for inclusion
in Annexes A, B or C of the Convention:**

Pentachlorobenzene

Summary of pentachlorobenzene proposal

Note by the Secretariat

1. The annex to the present note provides a summary prepared by the Secretariat of the proposal submitted by the European Union and its member States that are Party to the Stockholm Convention on Persistent Organic Pollutants for listing pentachlorobenzene in Annex A, B or C of the Stockholm Convention pursuant to paragraph 1 of Article 8 of the Convention. It has not been formally edited. The complete proposal is contained in document UNEP/POPS/POPRC.2/INF/5.

Possible action by the Committee

2. The Committee may wish:

(a) To consider the information provided in the present note and in document UNEP/POPS/POPRC.2/INF/5;

(b) To decide whether it is satisfied that the proposal fulfils the requirements of Article 8 and Annex D of the Convention;

(c) To develop and agree on, if it decides that the proposal fulfils the requirements referred to in subparagraph (b) above, a workplan for preparing a draft risk profile pursuant to paragraph 6 of Article 8.

* UNEP/POPS/POPRC.2/1.

Annex

Proposal for listing pentachlorobenzene in Annexes A, B or C of the Stockholm Convention on Persistent Organic Pollutants

Introduction

1. Pentachlorobenzene belongs to the group of chlorobenzenes. This substance has been used in the past as a pesticide, flame retardant, and in combination with PCBs in dielectric fluids. It is not clear whether it is still used as a pesticide or flame retardant on its own; however, it can be found as an impurity of pentachloronitrobenzene (quintozone) and other pesticides such as Clopyralid, Atrazine, Chlorothalonil, Dacthal, Lindane, pentachlorophenol, Picloram and Simazine. It may be emitted to the environment indirectly: as a result of waste incineration and barrel burning of household waste; in waste streams from pulp and paper mills, iron and steel mills, and petroleum refineries; and in activated sludge from waste water treatment facilities. Pentachlorobenzene is not produced commercially in the UNECE Europe any more (Belfroid et al. 2005).

2. This dossier provides the information required under paragraphs 1 and 2 of Annex D of the Stockholm Convention and is mainly based on:

(a) Van de Plassche, E.J., Schwegler, A.M.G.R., Rasenberg, M. and Schouten, A. 2002. Pentachlorobenzene. Dossier prepared for the third meeting of the UN-ECE Ad hoc Expert Group on POPs. Royal Haskoning report L0002.A0/R0010/EVDP/TL (<http://www.unece.org/env/popsxg/docs/2005/EU%20pentachlorobenzeen.pdf>);

(b) Belfroid, A., van der Aa, E. and Balk, F. 2005. Addendum to the risk profile of Pentachlorobenzene. Royal Haskoning report 9R5744.01/R0005/ABE/CKV/Nijm. (http://www.unece.org/env/popsxg/docs/2005/PeCB%20_def__NL.pdf).

3. These reviews and other references (as provided in document UNEP/POPS/POPRC.2/INF/5) serve as a source of further information referred to in paragraph 3 of Annex D of the Stockholm Convention on this candidate POP chemical.

1. Identification of the chemical

1.1 Names and registry numbers

4. CAS¹/IUPAC² chemical name: Pentachlorobenzene

Synonyms:	1,2,3,4,5-pentachlorobenzene; benzene, pentachloro-; quintochlorobenzene; PeCB
-----------	---

Trade names:	None
--------------	------

CAS registry number:	608-93-5
----------------------	----------

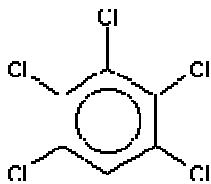

EINECS ³ Number:	210-172-0
-----------------------------	-----------

1.2 Structure

1 Chemical Abstracts Service.

2 International Union of Pure and Applied Chemistry.

3 European Inventory of Existing Chemical Substances.

Molecular formula: C_6HCl_5

Molecular weight: 250.32 g/mol

2 Persistence

5. According to CEPA (1993) pentachlorobenzene (PeCB) can be photo-oxidized in the atmosphere, largely through reactions with hydroxyl (OH) radicals. There are no experimental data on atmospheric degradation, but the estimated half-life of PeCB is 45 to 467 days. Vulykh et al. (2005) estimate a half life in air of 65 days based on modelling data.

6. Although photodegradation in surface water is fast under sunlight irradiation (41% loss after 24 h), under field conditions the strong adsorption to solids may counteract this process (HSDB, February 2000). The half-life of PeCB in surface water was estimated to range from 194 to 1 250 days, while the estimated half-life for the anaerobic biodegradation in deeper water ranged from 776 to 1 380 days (CEPA, 1993).

7. Although anaerobic degradation occurs, half-lives for anaerobic degradation are still high. In sediment cores at Ketelmeer (the Netherlands), PeCB is apparently persistent, i.e., several years in the presence of native anaerobic microflora. A special mixed culture of anaerobic species showed a half-life of several days (Beurskens et al., 1994). Beck and Hansen (1974) observed a half-life of 194-345 days in soils.

8. In sediments and soils oxygen is generally scarce, which favours reductive dechlorination. Information on PeCB's degradation pathways is scarce. Most work for the higher chlorinated benzenes has been done on hexachlorobenzene, for which the first step in the proposed pathway is dechlorination to PeCB. Further dechlorination leads to monochlorobenzene (Van Agteren et al., 1998).

9. Min-Jian Wang et al. (1994, 1995) have done research on the behaviour and fate of chlorobenzenes (CB) in spiked and sewage sludge-amended soil from a long-term (from 1942 to 1961) agricultural experiment. Their conclusion is that about 10% of the applied total CBs became recalcitrant and that the main loss of CBs is by volatilisation. Half-lives of 219 and 103 days were reported for PeCB. It is expected that if PeCB is released to soil, it will absorb strongly to the soil and will not leach to the groundwater. It will not be expected to be subject to significant hydrolysis or biodegradation.

10. PeCB appear to be very persistent in soils, water and the atmosphere, based on actual measurements and experimental estimates.

3 Bioaccumulation

11. Measured and calculated $\log K_{ow}$ values for PeCB vary between 4.8 and 5.18. The measured BCF values based on whole body wet weight vary between 3 400 and 13 000. In many cases the BCF value exceeds the limit of 5 000, indicating a high potential for accumulation. Van de Plassche (1994) reviewed the information on bioconcentration in fish and molluscs for PeCB and derived a geometric mean BCF for fish of 5 300. CEPA (2002) reports BAFs of 810 in mussels (*Mytilus edulis*), 20 000 in rainbow trout (*Oncorhynchus mykiss*) and 401 000 for earthworms (*Eisenia andrei*).

4 Potential for long-range environmental transport

12. The vapour pressure of PeCB is 2.2 Pa at 25 °C and the calculated half-life in air is 277 days, ranging from 45 to 467 days (Van de Plassche et al. 2002). These two properties seem to indicate that PeCB is very likely to undergo long range environmental transport (LRET). In table 1 the values for water solubility, vapour pressure and Henry's Law Constant for PeCB can be compared with the maximum and the minimum for currently listed POPs. Henry's Law Constant, a key property to

determine if there is risk of long range environmental transport for a substance, is well inside the range set by the other POPs, which also supports the potential for long-range transport of PeCB.

Table 1: Water solubility (WS), vapour pressure (VP) and Henry's Law Constant (HLC) for pentachlorobenzene and currently listed POPs.

Substance	WS mg/L	VP Pa	HLC Pa m ³ /mol
PeCB	0.56 *	2.2 *	983.4 **
POP-min	1.2 x 10 ⁻³ (DDT)	2.5 x 10 ⁻⁵ (DDT)	4 x 10 ⁻² (endrin)
POP-max	3.0 (toxaphene)	27 (toxaphene)	3 726 (toxaphene)
POP-2 nd max	0.5 (dieldrin)	0.04 (heptachlor)	267 (heptachlor)

* Van de Plassche et al. 2002

** Calculated from VP and WS

13. There is also evidence based on modelling data. Mantseva et al. (2004) developed a multi-compartment transport model for the evaluation of long-range atmospheric transport and deposition of POPs. Based on this model assessment a transport distance in Europe of over 8 000 km has been calculated for PeCB. The modelling performed by Vulykh et al. (2005) gives a similar value of 8 256 km.

14. PeCB has been detected in air samples collected at 40 sampling stations in North America (Canada, USA, Mexico, Belize and Costa Rica), including 5 Arctic stations (Shen et al. 2005). The air concentrations were almost uniform across North America with an average concentration of 0.045 ng/m³ and a range 0.017 – 0.138 ng/m³. According to the authors, this small spatial variability across the northern hemisphere indicates that PeCB has a very long atmospheric residence time, which allows it to become widely distributed in the global atmosphere.

15. In Sweden, PeCB was also detected in all 8 analyzed air samples (median 0.033 ng/m³) and in two atmospheric deposition samples (max 0.16 ng/m²/day) collected in the Stockholm area (Kaj and Palm, 2004).

16. In all six bottom sediments from harbours of northern Norway and the Russian Kola Peninsula in the Arctic, PeCB ranged from 2-5 µg/kg dry weight (AMAP 2004). These concentrations are similar to those detected in 3 of the 20 freshwater sediment samples collected in 2002 in the Stockholm area (Sternbeck et al. 2003). The maximum concentration was 6 µg/kg dry weight. In another study, PeCB was detected in Swedish sediment samples (4 out of 6 samples, median 1 µg/kg dry weight) (Kaj and Palm 2004).

17. PeCB was detected in fish muscle collected in 2002 at Swedish marine and freshwater sites regarded as uncontaminated. Kaj and Dusan (2004) measured 2.2 ng PeCB/g lipid weight in herring from one location and a maximum 16 ng PeCB/g lipid weight in perch from two other locations.

18. In the Netherlands, PeCB was detected in all 10 flounder liver samples collected in 1996, including flounder from two relatively unpolluted reference locations (De Boer et al., 2001). The highest concentration was 1100 µg/kg lipid weight (280 µg/kg wet weight), and at the reference location 3 ng/g lipid weight (0.64 ng/g wet weight). Also in 2003, PeCB was detected in 50% of the freshwater fish samples (eel and pike perch) in concentrations ranging between 1-10 ng/g wet weight (Van Leeuwen et al. 2004).

19. PeCB has been detected in different arctic species. Vorkamp et al. (2004) analysed PeCB in biota from Greenland and measured the following concentrations in lipid (lw) and wet weight (ww):

- (a) Ptarmigan liver approximately 23 ng/g lw (1.5 ng/g ww);
- (b) Kittiwake muscle approximately 8 ng/g lw (1.1 ng/g ww);
- (c) Musk ox blubber approximately 0.32 ng/g lw (0.29 ng/g ww);
- (d) Arctic char approximately 3.9 ng/g lw (0.07 ng/g ww).

20. A study by Verreault et al. (2005) showed that PeCB was present in the adipose tissue of polar bears in a variety of Arctic populations (Alaska, Canada, East Greenland and Svalbard Islands). PeCB was also detected in all 15 plasma and fat samples of polar bears from the arctic Svalbard Islands with an average concentration of 7.9 and a maximum of 13.3 ng/g wet weight (Gabrielsen et al. 2004). PeCB was detected in soils and mosses from coastal areas of Victoria Land (Antarctica) (Borghini et al. 2005). Concentrations in the six mosses samples varied between 1-2.4 ng/g dry weight and in the four soil samples between 0.4 and 1.3 ng/g dry weight.

21. The modelling and monitoring data, as well as PeCB's chemical properties, indicate that this substance has a considerable potential for long-range environmental transport.

5 Adverse effects

22. PeCB is classified within the EU as "Harmful if swallowed" and "Very toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment". A review of the different adverse effects of PeCB can be found in the report by Van de Plassche et al. (2002). PeCB has been tested on rats and mice. Acute toxicity tests were available after oral and dermal exposure. The lowest LD50 value after oral exposure was for rats, i.e. 250 mg/kg body weight. In a study in which the rats were orally exposed to 250 mg/kg body weight/day during 3 days, some liver functions were increased. To determine a dermal LD50 one concentration (i.e. 2500 mg/kg body weight) was tested on rats, but no toxic effects were seen at this dose. In a subchronic toxicity study oral uptake of 25 mg/kg body weight and more resulted in effects on the liver and kidneys (increased weight and histopathological changes). A concentration of 12.5 mg/kg body weight has been determined as the no-observed-effect-concentration (NOEC). In a 15 day study by McDonald for the National Toxicology Program (1991) the no-observed effect levels (NOELs) for histologic lesions were 33 mg/kg for male rats and 330 mg/kg body weight for female rats. The NOEL for histologic lesions in female mice was 100 mg/kg body weight. A NOEL was not reached for male mice.

23. PeCB was classified in Group V (inadequate data for evaluation) of the classification scheme for carcinogenicity (CEPA, 1993). Regarding teratogenic effects, suckling pups from mothers fed a dose of 12.5 mg/kg body weight developed tremors 4 - 14 days after birth. At a maternal dose of 6.3 mg/kg body weight this effect did not occur in pups. In another study, pregnant female rats were administered PeCB at levels of 50, 100 and 200 mg/kg body weight daily on day 6 through 15 of gestation. The number of live foetuses was not affected; however, the mean foetal weight was decreased in the highest dose group (Sloof et al., 1991).

24. Acute toxicity data for freshwater organisms is available on algae, crustaceans and fish. Chronic toxicity data is only available on crustaceans and fish. For marine organisms, only acute toxicity data is available for fish. Based on the data available, marine and freshwater organisms do not seem to differ significantly in sensitivity to PeCB. The lowest LC50 value for fresh water organisms is 250 µg/L for fish. The lowest NOEC reported is 10 µg/L for crustaceans.

25. Based upon acute and subchronic animal tests, PeCB is probably moderately toxic to humans and based on experiments with aquatic species, toxic for a range of aquatic organisms.

6 Statement of the reasons for concern

26. The proposal of the European Union and its member States contains the following Statement of Concern:

"PeCB is persistent in soil, water and the atmosphere. It has been shown to bioconcentrate in different species and to be toxic to aquatic organisms. It is also widely found in humans and biota in the environment as a result of its long range transport.

Although its production seems to have ceased in Europe and North America, it is still present as an impurity in commercial pesticides which are still used, and it is unclear whether it may be used as a pesticide or flame retardant in other parts of the world. As PeCB can move in the atmosphere far from its sources, single countries or groups of countries alone cannot abate the pollution caused by it. Due to its harmful POP properties and risks related to its possible continuing production, use and releases to the environment, international action is warranted to control this pollution."
